1.1 nqft package

1.1.1 Submodules

1.1.2 nqft.functions module

This module contains global functions used in the expression and operation on Hubbard hamiltonian.

It is also used more globally to perform operations on data files containing spectral function.

`nqft.functions.add_column(file: str, column: array, idx: int) → None`

Insert new data to given text file as a column.

Parameters

- **file** (*str*, *default=None*) – File in which add column.
- **column** (*np.array*, *default=None*) – Data column to add.
- **idx** (*int*, *default=0*) – Index of the new column inside current file.

`nqft.functions.delta(j: int, k: int) → float`

Kronecker delta function.

Parameters

- **j** (*int*, *default=None*) – First indice.
- **k** (*int*, *default=None*) – Second indice.

Returns

-

Return type

float (0.0 or 1.0)

`nqft.functions.find_nearest(array, value) → int`

Finds index in given array of the closest value of parameter 'value'.

Parameters

- **array** (*array-like*, *shape=(m, n)*, *default=None*) – Array in which search for the value.
- **value** (*int*, *float*, *default=None*) – Value to search for in array.

Returns

idx – Index at which user can find the closest value in array.

Return type

int

`nqft.functions.flatten_fermi_arc(save_path='./nqft/Data/fermi_arc_data_1D/', type='text') → None`

Saves Peter's Fermi arc numpy 2D arrays files as 1D arrays numpy files so they can be read in Rust/C.

Parameters

- **save_path** (*str*, *default*="./nqft/Data/fermi_arc_data_1D/") – Path where to save flatten arrays.
- **type** (*str*, *default*="text") – Format in which save flattened arrays (ex: type="npz" leads to .npz files)

Return type

None

`nqft.functions.plot_hall(files=['./nqft/Data/hall.txt'], x='doping') → Figure`

Plots hall coefficient as a function of interaction.

Parameters

- **files** (*list[str]*, *size*=N, *default*=["./nqft/Data/hall.txt"]) – Text files to plot.
- **x** (*str*, *default*='doping') – Type of x coordinate used to plot (setting up the legend label).

`nqft.functions.read_fermi_arc(path='./nqft/Data/fermi_arc_data/') → dict`

Reads Peter's data on spectral weight at Fermi level for a given number of sites.

Parameters

path (*str*, *default*="./nqft/Data/fermi_arc_data/") – Path to data directory.

Returns

arcs – A dict containing all spectral functions.

Return type

dict, size=6

`nqft.functions.read_locals(shape: tuple[int], interaction: float) → dict`

Reads local model's spectral functions for given shape and electronic density.

Parameters

- **shape** (*tuple*, *size*=2, *default*=None) – Shape of the clusters.
- **filling** (*int*, *default*=None) – Number of electrons in each cluster.

Returns

spectrums – Dictionnary containing all spectrums (values) associated with a specific density (keys).

Return type

dict

`nqft.functions.scalar(m: Qobj, n=None) → float`

Computes scalar product for Fock space vectors such as

$\text{scalar}(m, n) = \langle m | n \rangle$.

Parameters

- **m** (*qutip.Qobj*, *default=None*) – Bra on which perform scalar product.
- **n** (*qutip.Qobj*, *default=None*) – Ket on which perform scalar product.

Returns

- – Result of scalar product.

Return type

int, float

1.1.3 nqft.hall_effect module

Hall effect in cuprates with an incommensurate collinear spin-density wave.

```
class nqft.hall_effect.Model(hoppings: tuple[float], broadening: float, omega=0.0, mus=(-4, 4, 0.02),
                             resolution=400, use_peters=False)
```

Bases: object

Model instance to determine Hall coefficient and density from tight-binding hamiltonian.

hoppings

Hopping amplitude coefficients.

Type

tuple, size=3, default=None

broadening

Lorentzian broadening module.

Type

float, default=None

omega

Frequency at which we observe the fermi surface.

Type

float, default=None

mus

Chemical potential interval values and the interval between each element of an hypothetical array.

Type

tuple, size=3, default=(-4, 4, 0.02)

resolution

Resolution of phase space (k_x, k_y).

Type

int, default=4

use_peters

Determines if model's based on Peter R. spectral functions (fermi arcs)

Type

bool, default=False

get_density() → array

Computes electron density.

Returns

density – Electron density.

Return type

np.array, size=M

get_hall_nb() → array

Computes Hall number.

Returns

n_H – Hall number.

Return type

np.array, size=M

plot_spectral_weight(*mu*: float, *key*=None) → Figure

Outputs the spectral weight as a 2D numpy array.

Returns

- - 2D graph of spectral weight.

Return type

plt.figure

sigma_ii(*variable*: str) → array

Computing longitudinal conductivity at zero temperature in the zero-frequency limit when interband transitions can be neglected.

Parameters

variable (str, default=None) – Axis on which compute conductivity.

Returns

conductivity

Return type

float

sigma_ij() → array

Computing transversal conductivity at zero temperature in the zero-frequency limit when interband transitions can be neglected.

Returns

conductivity

Return type

float

nqft.hall_effect.dE(*hop_amps*: tuple, *kx*: ndarray, *ky*: ndarray, *mu*: array) → tuple

Outputs model's energies and it's derivatives.

Parameters

- **hop_amps** (tuple, default=None) – Hopping amplitudes coefficients.
- **kx** (np.ndarray, shape=(N, N), default=None) – kx space as a 2D array.
- **ky** (np.ndarray, shape=(N, N), default=None) – ky space as a 2D array.
- **mu** (np.array, size=M, default=None) – Chemical potential values array.

Returns

E, dEs – Energies and it's derivatives in a tuple.

Return type

tuple, size=2

`nqft.hall_effect.fit_lin(x: array, a: float, b: float) → array`

Linear function.

`nqft.hall_effect.get_spectral_weight(omega: float, eta: float, E: ndarray) → ndarray`

Outputs the spectral weight as a 3D numpy array.

Parameters

- **omega** (*float*, *default=None*) – Frequency at which we observe the fermi surface.
- **eta** (*float* *default=None*) – Lorentzian broadening module.
- **E** (*np.ndarray*, *shape=(M, N, N)*, *default=None*) – Eigenenergies of the system as a 3D numpy array.

Returns

A – Spectral weight.

Return type

np.ndarray, shape=(M, N, N)

`nqft.hall_effect.timeit(func)`

1.1.4 nqft.hamiltonian module

This module tests Qutip python library functions, objects and attributes in the context of Hubbard model using square fermion networks.

class `nqft.hamiltonian.Network(sites_nb: int)`

Bases: object

A class representing a fermionic many-body problem Network

sites_nb

Number of sites of the network

Type

int, default=None

vaccum

Vaccum state of 2D Fock space.

Type

Qobj, shape=(2, 1)

creation

Creation operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

anihilation

Anihilation operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

number

Number operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

I

Identity operator.

Type

Qobj, shape=(2, 2)

get_e(*H*: Qobj, *states*: list) → float

Outputs a matrix element (energy) from the hamiltonian using given kets on which perform projection.

Parameters

- **H** (Qobj, shape=(4^{self.sites}, 4^{self.sites}), default=None) – Fermions network hamiltonian.
- **states** (array-like, shape=(2, 1), default=None) – Vectors used to process scalar product on H.
(ex: states=[bra, ket] as integers to convert from binary)

Returns

E – Representation of projected vectors on H (energy).

Return type

int

Examples

```
>>> N = Network(sites_nb=2)
>>> Hamiltonian = N.get_hamiltonian(model="Hubbard", U=2, t=1)
>>> N.get_e(H=Hamiltonian, states=[15, 15])
2.0
```

get_hamiltonian(*model*: str, *U*: int, ***kwargs*) → Qobj

Outputs the hamiltonian of fermion network using specified many-body model.

Parameters

- **model** (str, default=None) – Fermions network configuration.
- **U** (int, default=None) – Module of interaction between fermions.
- ****kwargs** –
 - t**: int, default=None
Probability amplitude for fermions to jump.

Returns**H** – Tensor object representing hamitonian for given ‘model’.**Return type**qutip.Qobj, shape=(4^{SITES}, 4^{SITES})

Examples

```
>>> N = Network(sites_nb=4)
>>> N.get_hamiltonian(model="Hubbard", U=1, t=1)
Quantum object: dims = [[2, 2, 2, 2, 2, 2, 2, 2],
[2, 2, 2, 2, 2, 2, 2, 2]], shape = (256, 256), type = oper,
isherm = True Qobj data =
[[ 0.  0.  0. ...  0.  0.  0.]
 [ 0.  0. -1. ...  0.  0.  0.]
 [ 0. -1.  0. ...  0.  0.  0.]
 ...
 [ 0.  0.  0. ...  3. -1.  0.]
 [ 0.  0.  0. ... -1.  3.  0.]
 [ 0.  0.  0. ...  0.  0.  4.]]
```

get_state(*state: int, type='ket'*) → Qobj

Gives array-like representation of given state using Qutip 'tensor' operation.

Parameters

- **state** (*int, default=None*) – Integer representing state number in Fock space.
- **type** (*str, default='ket'*) – Type of vector outputed (bra, ket)

Returns

bra, ket – Full vector representation.

Return type

qutip.Qobj, shape=(4^{SITES}, 1)

Examples

```
>>> N = Network(sites_nb=1)
>>> self.get_state(state=2)
Quantum object: dims = [[2, 2], [1, 1]], shape = (4, 1), type = ket
Qobj data =
[[0.]
 [0.]
 [1.]
 [0.]]
```

lanczos(*H: Qobj, iterations: int, init_state=None*) → tuple

Implementation of Lanczos algorithm for Network hamiltonian.

Parameters

- **H** (*Qobj, shape=(4^{self.sites}, 4^{self.sites}), default=None*) – Fermions network hamiltonian.
- **iterations** (*int, default=None*) – Number of iterations on which perform the algorithm.
- **init_state** (*QObj, shape=(4^{self.sites}, 1) default=random*) – Initial quantum state to start the first iteration.

Returns

-- Respectively the maximum eigenvalue and the associated eigenvector.

Return type

tuple, shape=(1, 2)

Examples

```
>>> N = Network(sites_nb=2)
>>> Hamiltonian = N.get_hamiltonian(model="Hubbard", U=1, t=1)
>>> N.lanczos(H=Hamiltonian, iterations=10)
(2.561552779602264, Quantum object: dims = [[10], [1]],
shape = (10, 1), type = ket Qobj data =
[[0.43516215]
 [0.78820544]
 [0.43516215]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]])
```

1.1.5 nqft.qcm module

This module is dedicated to ‘pyqcm’ experimentation.

```
class nqft.qcm.QcmModel(shape: tuple[int], filling: int, interaction: float, hoppings: tuple[float], broadening:
                        float, w: float, mu: float, resolution: int, tiling_shift: bool, show_spectrum=False,
                        overwrite=False)
```

Bases: object

Docs

```
get_cluster_averages(operators: list[str]) → dict
```

Computes single cluster operator averages.

Parameters

operators (list, default=None) – Operators to keep in output dictionary.

Returns

out_dict – Dictionary containing operator names as keys and tuples as values representing operator average and it’s variance.

Return type

dict

```
get_lattice_averages(operators: list[str]) → dict
```

Computes lattice operator averages.

Parameters

operators (list, default=None) – Operators on which get average.

Returns

_ – Dictionary containing operator names as keys and average as values.

Return type

dict

plot_spectrums(*peter_key*: str, *type*='contourf', *save*=False) → Figure

Opens spectrums from (2x2, 3x4, 4x4) models and Peters spectrums array to compare the plot for given parameters.

Parameters

- **peter_key** (str, default=None) – Determines which of Peter's array to compare. ('N24', 'N28', 'N30', 'N32', 'N36')
- **type** (str, default='contourf') – Spectral plot type (contourf, pcolormesh).
- **save** (bool, default=False) – Saves or not the output plot.

Returns

–

Return type

matplotlib.pyplot.Figure object

nqft.qcm.build_matrix(*shape*: tuple) → list

Gives a coordinates matrix of a cluster having shape[0]*shape[1] sites.

Parameters

shape (tuple, shape=(2, 1), default=None) – Shape of sites network.

Returns

array – Nested lists of coordinates.

Return type

list, shape=(**shape*)

Examples

```
>>> build_matrix(shape=(2, 2))
[[0, 0, 0], [1, 0, 0], [0, 1, 0], [1, 1, 0]]
```

nqft.qcm.get_hall_coeff(*spectral_weight*: ndarray, *hoppings*: tuple[float], *x_coord*=None, *file*='./nqft/Data/hall.txt') → float

Computes Hall coefficient for given parameters and writes it to a file using specified x coordinate.

Parameters

- **spectral_weight** (np.ndarray, shape=(N, M), default=None) – Spectral function used to compute Hall coefficient.
- **hoppings** (tuple[float], size=3, default=None) – Hopping amplitudes corresponding to spectral function.
- **x_coord** (float/int, default=None) – X coordinate to use if writing Hall coefficient to a file. (Makes plotting easier and faster)
- **file** (str, default='./nqft/Data/hall.txt') – Path to file in which write Hall coefficient and given x coord.

Returns

n_h – Hall coefficient as a float.

Return type

float

1.1.6 Module contents
