1.1 nqft package

1.1.1 Submodules

1.1.2 nqft.functions module

This module contains global functions used in the expression and operation on Hubbard hamiltonian.

It is also used more globally to perform operations on data files containing spectral function.

`nqft.functions.add_column(file: str, column: array, idx: int) → None`

Insert new data to given text file as a column.

Parameters

- **file** (*str*, *default=None*) – File in which add column.
- **column** (*np.array*, *default=None*) – Data column to add.
- **idx** (*int*, *default=0*) – Index of the new column inside current file.

`nqft.functions.delta(j: int, k: int) → float`

Kronecker delta function.

Parameters

- **j** (*int*, *default=None*) – First indice.
- **k** (*int*, *default=None*) – Second indice.

Returns

-

Return type

float (0.0 or 1.0)

Examples

```
>>> delta(1, 1)
1.0
>>> delta(0, 1)
0.0
```

`nqft.functions.find_nearest(array, value) → int`

Finds index in given array of the closest value of parameter ‘value’.

Parameters

- **array** (*array-like, shape=(m, n), default=None*) – Array in which search for the value.
- **value** (*int, float, default=None*) – Value to search for in array.

Returns

idx – Index at which user can find the closest value in array.

Return type

int

Examples

```
>>> a = np.array([0, 1, 2, 3, 4, 5, 6])
>>> find_nearest(a, 3)
3
>>> b = np.array([0.0, 1.111, 2.5, 2.6])
>>> find_nearest(b, 2.0)
2
```

`nqft.functions.flatten_fermi_arc(save_path='./nqft/Data/fermi_arc_data_1D', size=36, res=200, type='text') → None`

Saves Peter’s Fermi arc numpy 2D arrays files as 1D arrays numpy files so they can be read in Rust/C.

Parameters

- **save_path** (*str, default='./nqft/Data/fermi_arc_data_1D/'*) – Path where to save flatten arrays.
- **size** (*int, default=36*) – Number of sites of studied model.
- **res** (*int, default=200*) – Resolution of momentum space.
- **type** (*str, default="text"*) – Format in which save flattened arrays (ex: type=”`numpy`” leads to `.npy` files)

Return type

None

`nqft.functions.make_cmap(ramp_colors: list) → LinearSegmentedColormap`

Makes a custom colormap to use in matplotlib ‘contourf’ or any plot using a colorbar.

Parameters

ramp_colors (*list, default=None*) – Hex code(s) of colors to use when making the colormap.

Returns**color_ramp** – Custom colormap**Return type**

LinearSegmentedColormap

`nqft.functions.read_fermi_arc(path='./nqft/Data/fermi_arc_data', size=36, res=200) → dict`

Reads Peter's data on spectral weight at Fermi level for a given number of sites.

Parameters

- **path** (*str*, *default*="./nqft/Data/fermi_arc_data/") – Path to data directory.
- **size** (*int*, *default*=36) – Number of sites of studied model.
- **res** (*int*, *default*=200) – Resolution of momentum space.

Returns**arcs** – A dict containing all spectral functions.**Return type**

dict, size=6

`nqft.functions.scalar(m: Qobj, n=None) → float`

Computes scalar product for Fock space vectors such as

 $\text{scalar}(m, n) = \langle m | n \rangle$.**Parameters**

- **m** (*qutip.Qobj*, *default*=None) – Bra on which perform scalar product.
- **n** (*qutip.Qobj*, *default*=None) – Ket on which perform scalar product.

Returns

– Result of scalar product.

Return type

int, float

1.1.3 nqft.hall_effect module

Hall effect in cuprates with an incommensurate collinear spin-density wave.

```
class nqft.hall_effect.Model(hoppings: tuple[float], broadening: float, omega=0.0, mus=(-4, 4, 0.02),
                             resolution=600, use_peters=(None, 200), use_filter=False)
```

Bases: object

Model instance to determine Hall coefficient and density from tight-binding hamiltonian.

hoppings

Hopping amplitude coefficients.

Type

tuple, size=3, default=None

broadening

Lorentzian broadening module.

Type

float, default=None

omega

Frequency at which we observe the fermi surface.

Type

float, default=None

mus

Chemical potential interval values and the interval between each element of an hypothetical array.

Type

tuple, size=3, default=(-4, 4, 0.02)

resolution

Resolution of phase space (k_x, k_y).

Type

int, default=600

use_peters

Determines if model's based on Peter R. spectral functions. User must choose between None, 36 and 64 for the first element representing the number of sites and between 200 and 500 for the second element representing the resolution of momentum space.

(Note: User must let first element as 'None' to use non-interacting spectrums normally.)

Type

tuple[int], default=(None, 200)

use_filter

Determines if spectral weights will be filtered using diamond shape filter to create artificial Fermi arcs.

Type

bool, default=False

get_density() → array

Computes electron density.

Returns

density – Electron density.

Return type

np.array, size=M

get_hall_nb() → array

Computes Hall number.

Returns

n_H – Hall number.

Return type

np.array, size=M

plot_hall() → Figure

Outputs a plot of the Hall coefficient as a function of doping (1 - density).

Returns

- – Graph of Hall number as a function of hole doping.

Return type

plt.Figure

plot_spectral_weight(*mu*: float, *size*=36, *key*=None) → Figure

Outputs a matplotlib figure containing 3 subplots. Left one represents the spectral function of non-interacting model. Center one the spectrum coming from Peter's article. Right one the superposition of the firsts.

Parameters

- **mu** (float, default=None) – Chemical potential at which we observe spectral function.
- **size** (int, default=36) – Size of Peter's model used to compare with non-interacting model.
- **key** (str, default=None) – Key of the dictionary containing Peter's spectrums. For example, the 64 sites model has ('N48', 'N52', 'N56', 'N60' and 'N64').

Returns

-- 2D graphs of spectral weights.

Return type

plt.figure

sigma_ii(*variable*: str) → array

Computing longitudinal conductivity at zero temperature in the zero-frequency limit when interband transitions can be neglected.

Parameters

variable (str, default=None) – Axis on which compute conductivity. (ex: 'x' or 'y')

Returns

conductivity

Return type

np.array, size=M

sigma_ij() → array

Computing transversal conductivity at zero temperature in the zero-frequency limit when interband transitions can be neglected.

Returns

conductivity

Return type

np.array, size=M

nqft.hall_effect.get_energies(*hops*: tuple[float], *kx*: ndarray, *ky*: ndarray, *mus*: array) → tuple

Outputs model's energies and it's derivatives.

Parameters

- **hops** (tuple, default=None) – Hopping amplitudes coefficients.
- **kx** (np.ndarray, shape=(N, N), default=None) – kx space as a 2D array.
- **ky** (np.ndarray, shape=(N, N), default=None) – ky space as a 2D array.
- **mus** (np.array, size=M, default=None) – Chemical potential values array.

Returns

E, dEs – Energies and it's derivatives in a tuple.

Return type

tuple[np.ndarray, dict], size=2

Examples

```

>>> hops = (1.0, -0.3, 0.2)
>>> ks, mus = np.linspace(-np.pi, np.pi, 2), np.linspace(-4, 4, 4)
>>> kx, ky = np.meshgrid(ks, ks)
>>> get_energies(hops, kx, ky, mus)
(
  array([[8.4, 8.4],
        [8.4, 8.4],
        [5.73333333, 5.73333333],
        [5.73333333, 5.73333333],
        [3.06666667, 3.06666667],
        [3.06666667, 3.06666667],
        [0.4, 0.4],
        [0.4, 0.4]]),
  {
    'dE_dx': array([[-1.95943488e-16, 1.95943488e-16],
                   [-1.95943488e-16, 1.95943488e-16]]),
    'ddE_dxx': array([[-1.6, -1.6],
                      [-1.6, -1.6]]),
    'dE_dy': array([[-1.95943488e-16, -1.95943488e-16],
                    [1.95943488e-16, 1.95943488e-16]]),
    'ddE_dyy': array([[-1.6, -1.6],
                      [-1.6, -1.6]]),
    'ddE_dxdy': array([[-0., -0.],
                       [-0., -0.]])
  }
)

```

`nqft.hall_effect.get_spectral_weight(omega: float, eta: float, E: ndarray, filter=False) → tuple[numpy.ndarray]`

Outputs the spectral weight as a 3D numpy array.

Parameters

- ***omega*** (*float*, *default=None*) – Frequency at which we observe the fermi surface.
- ***eta*** (*float*, *default=None*) – Lorentzian broadening module.
- ***E*** (*np.ndarray*, *shape*=(*M*, *N*, *N*), *default=None*) – Eigenenergies of the system as a 3D numpy array.
- ***filter*** (*bool*, *default=False*) – Determines if we use diamond filter over spectral weights.

Returns

A, diag_line – Spectral weight and diamond line array to plot over.

Return type

tuple[`np.ndarray`], size=2

Examples

```

>>> hops = (1.0, -0.3, 0.2)
>>> ks, mus = np.linspace(-np.pi, np.pi, 2), np.linspace(-4, 4, 4)
>>> kx, ky = np.meshgrid(ks, ks)
>>> E, dEs = get_energies(hops, kx, ky, mus)
>>> get_spectral_weight(0.0, 0.05, E)
(
  array([[0.00022555, 0.00022555],
         [0.00022555, 0.00022555],
         [0.00048414, 0.00048414],
         [0.00048414, 0.00048414],
         [0.00169189, 0.00169189],
         [0.00169189, 0.00169189],
         [0.0979415 , 0.0979415 ],
         [0.0979415 , 0.0979415 ]]),
  array([[0., 0.],
         [0., 0.]])
)

```

`nqft.hall_effect.timeit(func)`

1.1.4 nqft.hamiltonian module

This module tests Qutip python library functions, objects and attributes in the context of Hubbard model using square fermion networks.

class `nqft.hamiltonian.Network(sites_nb: int)`

Bases: object

A class representing a fermionic many-body problem Network

sites_nb

Number of sites of the network

Type

int, default=None

vaccum

Vaccum state of 2D Fock space.

Type

Qobj, shape=(2, 1)

creation

Creation operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

anihilation

Anihilation operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

number

Number operator in second quantization formalism.

Type

Qobj, shape=(2, 2)

I

Identity operator.

Type

Qobj, shape=(2, 2)

get_e(*H: Qobj, states: list*) → float

Outputs a matrix element (energy) from the hamiltonian using given kets on which perform projection.

Parameters

- **H** (*Qobj, shape=(4^{self.sites}, 4^{self.sites}), default=None*) – Fermions network hamiltonian.
- **states** (*array-like, shape=(2, 1), default=None*) – Vectors used to process scalar product on H.

(ex: states=[bra, ket] as integers to convert from binary)

Returns

E – Representation of projected vectors on H (energy).

Return type

int

Examples

```
>>> N = Network(sites_nb=2)
>>> Hamiltonian = N.get_hamiltonian(model="Hubbard", U=2, t=1)
>>> N.get_e(H=Hamiltonian, states=[15, 15])
2.0
```

get_hamiltonian(*model: str, U: int, **kwargs*) → Qobj

Outputs the hamiltonian of fermion network using specified many-body model.

Parameters

- **model** (*str, default=None*) – Fermions network configuration.
- **U** (*int, default=None*) – Module of interaction between fermions.
- ****kwargs** –

t: int, default=None

Probability amplitude for fermions to jump.

Returns

H – Tensor object representing hamitonian for given ‘model’.

Return type

qutip.Qobj, shape=(4^{SITES}, 4^{SITES})

Examples

```
>>> N = Network(sites_nb=4)
>>> N.get_hamiltonian(model="Hubbard", U=1, t=1)
Quantum object: dims = [[2, 2, 2, 2, 2, 2, 2, 2],
[2, 2, 2, 2, 2, 2, 2, 2]], shape = (256, 256), type = oper,
isherm = True Qobj data =
[[ 0.  0.  0. ...  0.  0.  0.]
 [ 0.  0. -1. ...  0.  0.  0.]
 [ 0. -1.  0. ...  0.  0.  0.]
 ...
 [ 0.  0.  0. ...  3. -1.  0.]
 [ 0.  0.  0. ... -1.  3.  0.]
 [ 0.  0.  0. ...  0.  0.  4.]]
```

get_state(*state: int, type='ket'*) → Qobj

Gives array-like representation of given state using Qutip 'tensor' operation.

Parameters

- **state** (*int, default=None*) – Integer representing state number in Fock space.
- **type** (*str, default='ket'*) – Type of vector outputed (bra, ket)

Returns

bra, ket – Full vector representation.

Return type

qutip.Qobj, shape=(4^{SITES}, 1)

Examples

```
>>> N = Network(sites_nb=1)
>>> self.get_state(state=2)
Quantum object: dims = [[2, 2], [1, 1]], shape = (4, 1), type = ket
Qobj data =
[[0.]
 [0.]
 [1.]
 [0.]]
```

lanczos(*H: Qobj, iterations: int, init_state=None*) → tuple

Implementation of Lanczos algorithm for Network hamiltonian.

Parameters

- **H** (*Qobj, shape=(4^{self.sites}, 4^{self.sites}), default=None*) – Fermions network hamiltonian.
- **iterations** (*int, default=None*) – Number of iterations on which perform the algorithm.
- **init_state** (*QObj, shape=(4^{self.sites}, 1) default=random*) – Initial quantum state to start the first iteration.

Returns

- - Respectively the maximum eigenvalue and the associated eigenvector.

Return type

tuple, shape=(1, 2)

Examples

```
>>> N = Network(sites_nb=2)
>>> Hamiltonian = N.get_hamiltonian(model="Hubbard", U=1, t=1)
>>> N.lanczos(H=Hamiltonian, iterations=10)
(2.561552779602264, Quantum object: dims = [[10], [1]],
shape = (10, 1), type = ket Qobj data =
[[0.43516215]
 [0.78820544]
 [0.43516215]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]
 [0.         ]])
```

1.1.5 nqft.monte_carlo module

`nqft.monte_carlo.build_h(shape: tuple[int], eps: array, hops: array) → ndarray`[Docs](#)

1.1.6 nqft.qcm module

This module is dedicated to ‘pyqcm’ experimentation.

```
class nqft.qcm.QcmModel(shape: tuple[int], filling: int, interaction: float, hoppings: tuple[float], broadening:
                        float, w: float, mu: float, resolution: int, tiling_shift: bool, show_spectrum=False,
                        overwrite=False)
```

Bases: object

QcmModel instance to make the usage of ‘pyqcm’ easier.

shape

Shape of the source cluster as: (rows, columns).

Type

tuple[int], size=2, default=None

filling

Number of electrons inside each cluster.

Type

int, default=None

interaction

Coefficient of interaction operator.

Type

float, default=None

hoppings

Hopping amplitudes coefficients.

Type

tuple[float], default=None

broadening

Lorentzian broadening module.

Type

float, default=None

w

Frequency at which we observe the fermi surfaces.

Type

float, default=None

mu

Chemical potential.

Type

float, default=None

resolution

Resolution of phase space (k_x, k_y).

Type

int, default=None

tiling_shift

Determines if super-vectors are shifted or exactly orthogonals.

Type

bool, default=None

show_spectrum

Determines if 'pyqcm.spectral.mdc' displays spectral function when it computes it.

Type

bool, default=False

overwrite

Determines if the script reuses an already computed model to do further calculations or if the script computes it from scratch.

Type

bool, default=False

get_cluster_averages(*operators: list[str]*) → dict

Computes single cluster operator averages.

Parameters

operators (*list*, *default=None*) – Operators to keep in output dictionary.

Returns

out_dict – Dictionary containing operator names as keys and tuples as values representing operator average and it's variance.

Return type

dict

get_lattice_averages(*operators: list[str]*) → dict

Computes lattice operator averages.

Parameters

operators (*list*, *default=None*) – Operators on which get average.

Returns

– Dictionary containing operator names as keys and average as values.

Return type

dict

plot_spectrums(*peter_key: str*, *type='contourf'*, *save=False*) → Figure

Opens spectrums from (2x2, 3x4, 4x3) models and Peters spectrums array to compare the plot for given parameters.

Parameters

- **peter_key** (*str*, *default=None*) – Determines which of Peter's array to compare. ('N24', 'N26', 'N28', 'N30', 'N32', 'N34', 'N36')
- **type** (*str*, *default='contourf'*) – Spectral plot type (contourf, pcolormesh).
- **save** (*bool*, *default=False*) – Saves or not the output plot.

Returns

–

Return type

matplotlib.pyplot.Figure object

nqft.qcm.build_matrix(*shape: tuple*) → list

Gives a coordinates matrix of a cluster having shape[0]*shape[1] sites.

Parameters

shape (*tuple*, *shape=(2, 1)*, *default=None*) – Shape of sites network.

Returns

array – Nested lists of coordinates.

Return type

list, shape=(**shape*)

Examples

```
>>> build_matrix(shape=(2, 2))
[[0, 0, 0], [1, 0, 0], [0, 1, 0], [1, 1, 0]]
```

nqft.qcm.get_hall_coeff(*spectral_weight: ndarray*, *hoppings: tuple[float]*, *x_coord=None*, *file='./nqft/Data/hall.txt'*) → float

Computes Hall coefficient for given parameters and writes it to a file using specified x coordinate.

Parameters

- **spectral_weight** (*np.ndarray*, *shape=(N, M)*, *default=None*) – Spectral function used to compute Hall coefficient.
- **hoppings** (*tuple[float]*, *size=3*, *default=None*) – Hopping amplitudes corresponding to spectral function.

- **x_coord** (*float/int*, *default=None*) – X coordinate to use if writing Hall coefficient to a file. (Makes plotting easier and faster)
- **file** (*str*, *default="./nqft/Data/hall.txt"*) – Path to file in which write Hall coefficient and given x coord.

Returns

n_h – Hall coefficient as a float.

Return type

float
